What's Out Tonight?

September 2019 Sky Chart

Instructions
Face North, South, East or West, then rotate the chart so your direction is at the bottom. Match the biggest stars on the chart to the brightest stars in the sky. The center of the chart is the top of the sky.

Planets
The position of any visible, naked-eye planet is indicated for the 15th of the month. If the planet moves significantly during a month, other positions will be noted with dates. The ECLIPTIC is the path of the Sun through the sky but the planets and Moon move along it, too. It passes through the constellations of the zodiac.

September 2019 Planet Notes
Venus, around the 15th, at magnitude ~3.9, sets in the west just 30 minutes after the Sun. Mars is still too close to the Sun to see in the night sky. Jupiter, at magnitude ~2.1, is in Ophiuchus and is low in the southwest when dark and sets in the west around 11:30 PM. Saturn, at magnitude +0.4, is in Sagittarius, and is low and near the southern meridian when dark and sets in the west around 1 AM.

Distances planets are from the Earth on the 15th of this month:
Venus: 158,000,000 miles, Mars: 158,000,000 miles, Jupiter: 491,000,000 miles, Saturn: 896,000,000 miles.
**September Notes**

At the top of the sky is CYGNUS & LYRA, each containing a star of the Summer Triangle, respectively, Deneb and Vega. The third, farther below is Altair in AQUILA. To the east of the Triangle is the Great Square, a part of PEGASUS. CYGNUS bathes in the Milky Way which flows on through SAGITTARIUS hanging above the southwest horizon. Just to the right of SAGITTARIUS' triangular base is the direction to the center of our Milky Way Galaxy where a giant black hole resides. Face north and above Polaris, from west to east are the head of DRACO, CEPHEUS and CASSIOPEIA. The Andromeda Galaxy, which is close to CASSIOPEIA can be seen with the naked eyes under dark skies.

Selected Clusters, Nebulae, Galaxies +

**Albireo.** This 3rd magnitude stars becomes two stars, a blue and gold splendor, in a telescope with just 50x.

**Andromeda Galaxy.** Companion to our Milky Way Galaxy. Distance: 2,400,000 ly / Diameter: 120,000 ly / Mag 3.5 / Spans 3° x 1°.

**Coathanger Cluster.** Ten stars that form the shape of a single-wire coathanger. In VULPECULA.

**IC4665.** A cluster of 30 stars that is best in binoculars. It spans an area larger than the Moon. In OPHIUCHUS.

**M4.** Globular Cluster. Distance: 7,200 ly / Diameter: 68 ly / Mag 5.6 / Spans 30'. Contains 10,000+ stars. In SCORPIUS.

**M6.** Similar to and above M7, this cluster also has 80 stars but it is a little fainter and 1/4 the size. In SCORPIUS.

**M7.** Ptolemy's Cluster. A great cluster, nice in binoculars or telescope. About 80 stars at magnitude 3.3 spanning an area larger than the Moon. Can see as a “patch” with eyes. In SCORPIUS.

**M11.** Wild Duck Cluster. Distance: 5,600 ly / Diameter: 23 ly / Mag 5.8 / Spans 14' / 200 stars.

**M13.** Globular Cluster. Distance: 21,000 ly / Diameter: 104 ly / Mag 5.8 / Spans 17'. Contains 500,000 stars. In HERCULES.

**M22.** Globular Cluster. Distance: 10,400 ly / Diameter: 88 ly / Mag 5.1 / Spans 29'. 100,000+ stars. In SAGITTARIUS.

**M57.** Ring Nebula (Planetary). Distance: 1360 ly / Diameter: 0.5 to 1 ly / Mag 9 / Spans 1.3'. In LYRA. Remnants of a dying star.

**Mizar.** Two stars with good eyes or binoculars. Three stars with a telescope at 50x. Located in the handle of the Big Dipper.

**Observing Tips**

If possible, observe at a dark location and when the Moon is not bright. A bright Moon will make it more difficult to see the stars and impossible to see clusters, nebulae and galaxies. Only a small telescope at lower magnifications, around 50x, is required to see the objects listed above. The planets and Moon are best observed with a telescope around 100x. To get a feel for the size of objects, the Moon extends 30' (30 arc minutes). The binocular objects are best with binoculars because these objects are large in size—telescopes have too much magnification.

**Meteor Showers**

Next up are the ORIONIDS which peak around October 21 with 20 meteors/hour.

**September Mythology**

For the Central Constellations, North to South

Arcas and his beautiful mother, Callisto were turned into the Little and Big Bears, Ursa Minor and Major because of jealous Juno, wife of promiscuous Jupiter.

During a war between the Titans and Olympians, DRACO, the Dragon was flung to the North and frozen in place by the cold.

King CEPHEUS and Queen CASSIOPEIA ruled Ethiopia. Their beautiful daughter ANDROMEDA is being rescued by PERSEUS from the Sea Monster, CETUS.

HERCULES, the Strongman, was tasked with 12 labors to fulfill for a virtuous life.

LYRA, the Lyre was invented by Mercury and mastered by Apollo’s son, Orpheus whose music had magical powers.

AQUILA is Jupiter’s Eagle that carries out tasks. SAGITTARIUS, the Archer is a warlike centaur.

CYGNUS, the Swan helped Helios find the pieces of his son, having fallen from the chariot that pulls the Sun across the sky.

AQUARIUS is the Water and Cup Bearer, a servant of the gods.

CAPRICORNUS is a “Seagoat,” the partially transformed, half-goat, half-fish body of the god Pan who got scared and hurriedly escaped the monster Typhoon in order to warn Jupiter. The word panic is derived from Pan.

PEGASUS, the Winged Horse is the deliverer of Jupiter’s thunderbolts.

**Moon Phases**

- First Quarter. Thursday, September 5, 10:10 pm, CDT
- Full Moon. Friday, September 13, 11:33 pm, CDT
- Third or Last Quarter. Saturday, September 21, 9:41 pm, CDT
- New Moon. Saturday, September 28, 1:26 pm, CDT

Clusters, Nebulae & Galaxies

An **Open Cluster** is a group of several to hundreds of stars that were born out of the same nebula cloud. A group often forms a pretty pattern. The Pleiades and Praesepe are great examples. Open clusters reside in our Milky Way Galaxy. Our Sun is no longer in its group.

**Globular Clusters** look like fuzzy balls because they contain tens of thousands of stars held together by their mutual gravity. All of the globulars that can be seen in the sky are part of our Milky Way Galaxy, and there are about 200 of them that surround our galaxy like a halo. M22 in SAGITTARIUS is a northern favorite.

A **Planetary Nebula** is an old term that has nothing to do with the planets. Instead, it is a round or symmetrical nebula that is the shed atmosphere of a dying star. At its center is a white dwarf star. When our Sun dies, it will create a planetary nebula. These objects have diameters of a few light years and are located in our galaxy. The Ring Nebula, M57, in LYRA is a favorite.

A **Nebula** is a giant hydrogen gas cloud that is located in our galaxy. Within these clouds, concentrations of gas can occur and gravitationally condense to form stars and accompanying planets. A set of stars created by a nebula is known as an Open Cluster. The Orion Nebula, M42 is a favorite. The nebulae we can see are inside our galaxy.

**Galaxies** contain billions of stars. All galaxies are beyond our Milky Way Galaxy, where our Sun resides. When you are observing a galaxy, you are looking through our galaxy into the true depths of the universe. The Andromeda Galaxy, M31 can be seen with the naked eye.

Double Stars

A Double Star is a star that looks like one star but when magnified sufficiently (from 6x to 200x), it separates into two or more stars. Some are very pretty because of contrasting colors. **Castor** in GEMINI is a favorite and **Albireo** in CYGNUS is well liked for its blue & gold colors.

Moon

Starting from New Moon, the Moon cycles through phases every 29 days, 12 hours, 44 minutes, 3 seconds. It is 2,160 miles in diameter and averages 239,000 miles from Earth. A New Moon is not visible in the sky because the Moon is positioned very close to the Sun. Solar eclipses occur at New Moon. The best time to observe the Moon is during a phase because the craters appear their sharpest near the terminator, the line that separates the lighted side (day side) from the dark side (night side).

Light Year (ly) & Nearest Stars

A Light Year (ly) is a unit of length and is equal to the distance light travels in one year. Since light moves at the rate of 186,282 miles a second, one light year is nearly 6 trillion miles long. The closest nightime star visible to the naked eye is **Alpha (α) Centauri** in the constellation CENTAURUS. Alpha Centauri shines brightly at magnitude −0.01 and is just 4.4 light years away. The very closest star is **Proxima** in CENTAURUS at just 4.22 ly away. It is too faint to see with the eyes because it shines at magnitude +11. The second closest star visible to the naked eye is **Sirius** at 8.6 ly followed by **Epsilon (ε) Eridani** at 10.5 ly and **Procyon** at 11.4 ly. There are several stars closer than these three but they are too faint to be seen with the naked eye.
